Background
The level of glucose in the blood can be measured by applying a drop of blood to a chemically treated, disposable ‘test-strip’, which is then inserted into an electronic blood glucose meter. The reaction between the test strip and the blood is detected by the meter and displayed in units of mg/dL or mmol/L. There are a number of different types of meters available, and all are slightly different. Take care when applying the general principles described in this article to the specific glucose meter you are using.

Why measure blood glucose?
• It can be used as a screening tool for diabetes mellitus (diabetes).
• It is an important tool in the assessment of the unwell patient, especially in the young or old.
• Potentially life-threatening extremes of blood glucose can be detected to enable the patient, carer or health worker to respond to high (hyperglycaemia) and low (hypoglycaemia) blood glucose by adjusting the diet or using insulin.

When to measure blood glucose
• Blood glucose should be measured whenever your patient with diabetes is feeling unwell in any way.
• In the diabetic patient, it should be measured before surgery to ensure that the patient is not going to become unwell during surgery and/or after general anaesthetic. Measure regularly until the patient is eating and drinking normally and blood glucose is stable.
• In newly diagnosed diabetes patients, more frequent measurements are needed, until blood glucose is stable.

NOTE: Blood glucose monitoring is done to measure the concentration of glucose in the blood (glycaemia) over time, and is important in the care of patients with diabetes mellitus. Information about individual patterns of blood glucose changes, gathered through blood glucose monitoring, can be used to plan meals, activities, and at what time of day to take insulin. The better the patient’s blood glucose control, the less likely it is that the diabetes will cause damage in the body and lead to complications such as loss of vision (due to diabetic retinopathy) and amputation.

You will need
• Blood glucose monitor
• Test strips (check that they are in date and have not been exposed to the air)
• Alcohol swab
• Single-use safety lancets or lancing device
• Gloves
• Cotton wool/gauze
• Sharps box
• Control solution for calibration

Method
Apply these general principles when using the different types of electronic blood glucose meters available.
• Ask the patient to sit down and explain what you are going to do.
• Wash your hands and put on gloves.
• Choose the site for the blood sample: usually the side of a finger, but the arm
Understanding and caring for a Schiotz tonometer

Ismael Cordero
Clinical Engineer, Philadelphia, USA. ismaelcordero@me.com

A Schiotz tonometer is an instrument for measuring the intraocular pressure (IOP). Although the Schiotz tonometer does not make as precise measurements as other types of tonometers, it is inexpensive, simple to use, durable, requires little maintenance, does not have electronics, does not require batteries, and can be stored for years between uses. These qualities make it well suited for screening and remote or mobile clinics.

The Schiotz tonometer consists of a hollow barrel with a concave footplate and a holder (Figure 1). A free-floating, rod-like plunger with a 5.5 gram weight attached fits inside the barrel. When held vertically on top of the eye, the plunger will move downwards by gravity and indent the cornea. This very small up-and-down movement is magnified by a lever arm to move a needle that gives a reading on a horizontal scale numbered arbitrarily 0–20. A firmer eye, due to a higher IOP, will result in a lower indentation and a lower reading on the scale.

Since the Schiotz tonometer does not measure pressure directly, a conversion table, supplied with the instrument, is used to translate scale readings into estimates of IOP in mmHg. To account for the range of pressure, other weights (typically 7.5 g and 10 g) are supplied that can be added to the plunger.

**Calibrating the blood glucose monitor**

- Calibrate the monitor and each new pack of test strips together.
- Calibrate the monitor each week.
- Place the control solution on a test strip and check that the value shown on the monitor matches the value on the bottle (or the pack of strips it accompanies). Record the calibration readings.
- If one is provided, use the check strip to make sure that the meter is working.

**Cleaning**

Cleaning of the barrel and the plunger should be done once a day to prevent the plunger from sticking to the barrel.

1. Remove the plunger and use gauze with alcohol to clean the plunger and tip.
2. Clean the inside of the barrel with an alcohol-soaked cotton swab and then with a dry cotton swab.
3. Clean the footplate with gauze and alcohol.
4. Allow it to dry and then place, disassembled, in its case.

In between patients, the Schiotz tonometer should be disinfected by soaking it in sodium hypochlorite.
